This thesis summarizes the metallogenetic mechanism of the Galinge skarn deposit based on integrated knowledge of tectonics, geochemistry, geochronology, petrology, mineralogy, thermodynamics and hydrothermal fluids. It also discusses the multistage growth characteristics of various skarn minerals in which the varying compositions reflect the evolution of the hydrothermal fluid. The multidisciplinary nature of this research sheds new light on reconstructing metallogenetic processes successfully. It outlines the main aspects of skarn zonation based on the dominant contents of the skarn minerals and the wall rock compositions. In addition, it focuses on volatile-rich minerals including tourmaline and hastingsite, highlighting the importance of the volatile component in the skarn deposit. Lastly, it describes the regional tectonic-magmatic evolutionary history to explain the metallogenic principles, which can be used to guide prospecting in the field.

How did the United States come to have its distinctive workplace-based health insurance system? Why did Progressive initiatives to establish a government system fail? This book explores the history of health insurance in the United States from its roots in the nineteenth-century sickness funds offered by industrial employers, fraternal organizations, and labor unions to the rise of such group plans as Blue Cross and Blue Shield in the mid-twentieth century. Historians generally view the failure to establish universal health insurance during the first half of the twentieth century as an indicator of the political clout of insurers, employers, unions, and physicians who thwarted Progressive efforts. But the explanation is actually simpler, John Murray contends in this book. Careful analysis of the workings of industrial sickness funds suggests that workers rejected plans for compulsory state insurance because they were largely content with existing private plans. Murray revises our understanding of the evolution of health care insurance in the United States and discusses the implications of that history for the ongoing debates of today.

Iron is a major constituent of the earth crust. However, under alkaline conditions commonly found in arid and semi-arid environments iron becomes unavailable to plants. When plants are affected by a shortage of iron their leaves become yellow (chlorotic), and both plant growth and crop yield are reduced. The roots of plants affected by iron deficiency may develop a series of responses directed to improve iron uptake, such as increased proton excretion and iron reduction capabilities or excretion of iron

chelators called siderophores. Iron deficiency affects major crops worldwide, including some of major economic importance such as fruit trees and others. Correction of iron deficiency is usually implemented through costly application of synthetic chelates. Since these correction methods are very expensive, the competitiveness of farmers is often reduced and iron deficiency may become a limiting factor for the maintenance, introduction or expansion of some crops. In spite of the many years devoted to the study of iron deficiency, the knowledge of iron deficiency in soils and plants is still fragmentary in many aspects. We have only incomplete information on the processes at the molecular level that make some plant species and cultivars unable to take and utilize iron from the soil, whereas other plants grow satisfactorily under the same conditions. Sponsored jointly by the American Society of Mechanical Engineers and International Material Management Society, this single source reference is designed to meet today's need for updated technical information on planning, installing and operating materials handling systems. It not only classifies and describes the standard types of materials handling equipment, but also analyzes the engineering specifications and compares the operating capabilities of each type. Over one hundred professionals in various areas of materials handling present efficient methods, procedures and systems that have significantly reduced both manufacturing and distribution costs. In Mom: An Owner's Manual, you'll find everything you ever wanted to know about how to raise a perfect Mom. The principal objective of this research project was to develop a methodology that would assist water distribution engineers estimating the optimum time to replace grey cast iron water mains. The methodology should integrate information on corrosion-induced pit dimensions, effective pipe wall thickness, residual strength of grey cast iron, corrosion rates and the mechanical behavior of metallic water mains. Secondary objectives within the project were: to determine the most effective and practical approaches to measure the residual strength of grey cast iron pipe; to determine whether current or near-term nondestructive testing technology could be used to produce the necessary information on corrosion pit dimensions; and to expand the current state of knowledge with respect to the mechanical behaviour of grey cast iron water mains. This manual explains what is presented on the nautical chart, highlights the utility of this information, describes the charting conventions used to depict features and items of interest, and provides some practical pointers on how this information is used. It is written to serve many types of users, ranging from operators of recreational vessels to those who drive "heavy iron." Abundant photographs and chart excerpts illustrate key points made in the text. All chart excerpts were current as of spring 1995. Since this manual was published, some charts may have been revised. Even if

these specific charts have been revised, the general points remain valid. It almost goes without saying that these chart excerpts should not be used for navigational purposes.
